07-15: $\text{ACF}_p$ is complete	4
07-30: $\text{Grp}$ is cocomplete	4

This is a diary-like note that recording what I have learnt that day, so I try to keep them short and readable instead of formal, but if further proofs or descriptions are needed then I would like to leave a pointer to my other notes.

## 2025

### 06-30: $F^\times$ is cyclic

For finite field  $F$ , the multiplicative group  $F^\times$  is cyclic. This result can be used to prove that every finite field is gained from a quotient like  $F_p[x]/(\pi(x))$ , for some prime  $p$  and monic irreducible  $\pi(x)$ .

**Main idea:** a group  $G$  is cyclic iff there is an element  $g$  such that  $h = g^k$  for any other element  $h$  and some  $k$ , so we must have  $\text{ord } g = |G|$ . But by Lagrange theorem we always have  $\text{ord } g \mid |G|$  for any  $g$  in  $G$ , so it suffices to prove  $|G| \leq \text{ord } g$ . Thanks to the lemma below, we have  $h^{\text{ord } g} = 1$  for all  $h$ . So the polynomial  $x^{\text{ord } g} - 1$  has  $|F^\times|$  roots, which implies  $|F^\times| \leq \text{ord } g$ .

**Lemma:** In finite abelian group, the order of every element divides the maximal order. (It's fun to prove)

Ref. Finite Field. Conrad.

### 07-05: Compact theorem (by Ultraproduct)

- Ultraproduct: suppose  $(A_i)_{i \in I}$  is a bunch of structure in language  $L$ , then we can construct a new structure  $\mathcal{A}$  using them, provided an ultrafilter  $\mathcal{U}$  on  $I$ :

$$\mathcal{A} := \prod_{\mathcal{U}} A_i := \left( \prod_{i \in I} A_i \right) / \sim_{\mathcal{U}}.$$

- Los theorem: A formula is true in an ultraproduct, if and only if this formula is true in *many* smaller models which are used to make that ultraproduct. ("many" is defined by the ultrafilter.)
- Proof of Compact theorem: The model you want is the ultraproduct  $\prod_{\mathcal{U}} A_i$  where  $(A_i)_{i \in I}$ , which is indexed by the set  $I$  of all finite sub-theory of given theory  $T$ , are models of  $i \in I$  (by assumption these models must exist). To prove all formula  $\varphi$  in  $T$  are valid in that ultraproduct, one consult for Los theorem. (The ultrafilter needed by Los theorem can just be solved out by your desire of "making  $\mathcal{A}$  a model of  $T$ ".)

A little interesting result: Suppose  $\mathcal{U}_A$  is an ultrafilter generated by  $A$  on  $I$  (thus is principle), then

$$\{\mathcal{U}_A \subset B : B \text{ ultrafilter on } I\} \simeq \{V : V \text{ ultrafilter on } A\}.$$

This can be used to prove every principle ultrafilter is generated by a singleton in  $\mathcal{P}(I)$  i.e., by a single subset of  $I$ , or equivalently, every non-principle ultrafilter must contain the Frechet filter (consists of precisely all “cofinite” subsets of  $I$ ) as a subset.

## 07-06: $\mathbb{C}$ is the ultraproduct of $\left(\overline{\mathbb{F}_p}\right)_{p \text{ prime}}$

Do not know why yet. Can not even ensure the correctness, but I think...

## 07-07: $\text{Ran}_G G$ is a monad if it exists. Category admits arbitrary large limit must be a poset.

This is the construction of so-called **codensity** monad of an arbitrary functor  $G : A \rightarrow B$ , and the monadness can be proved in a clever way:

Define a category  $r_G$  whose:

- Objects:  $(X : B \rightarrow B, x : XG \Rightarrow G)$ , i.e., right extensions of  $G$ ;
- Morphisms between  $(X, x)$  and  $(Y, y)$ : Natural transformations  $\eta : X \Rightarrow Y$  which compatible with  $x$  and  $y$ .

And  $(r_G, \text{id}_B, \circ)$  is a (strict) monoidal category.

Then we find:  $\text{Ran}_G G$  is the terminal object in  $r_G$ ! So by common abstract nonsense argument, it has an unique monoid structure.

## 07-12: Adjoint Functor Theorem (and the free group functor)

In this section we fix a Grothendieck universe  $\mathbb{U}$  and all “complete” are interpreted as “ $\mathbb{U}$ -small complete”.

**Adjoint Functor Theorem:** For  $G : \mathcal{A} \rightarrow \mathcal{X}$  a continuous functor with complete domain  $\mathcal{A}$ , it has a *left adjoint*  $F : \mathcal{X} \rightarrow \mathcal{A}$  if and only if the notorious solution set condition is satisfied: For all  $x \in \mathcal{X}$  there is a bunch of objects  $a_i^x \in \mathcal{A}$  indexed by a small set such that there are a bunch of morphisms  $\eta_i^x : x \rightarrow Ga_i^x$  which form an initial class in the comma category  $(x \downarrow G)$ .

The solution set condition is just a combination of two *small* facts:

1. For a *small complete* category with *small* hom-sets, a initial class produce the initial object (tricky);
2. The unit of an adjunction  $\eta : \text{Id}_{\mathcal{X}} \Rightarrow GF$  is made up of initial objects of comma categories  $(x \downarrow G)$  for all  $x \in \mathcal{X}$  (ordinary observation).

The solution set condition is just the result of applying fact 1 to fact 2. And, as your expectation,  $Fx := a_x$ .

I have a sense that this solution set condition is just a rephrasement of  $\text{Ran}_G \text{Id}_{\mathcal{A}}$  is a absolute right Kan extension.

**Application:** We now show the existence of free group functor: By the Adjoint Functor Theorem and the well known fact that **Grp** is complete, we just need to construct an initial class for each set  $S \in \mathbf{Set}$ . In the following proof,  $U : \mathbf{Grp} \rightarrow \mathbf{Set}$  is the forgetful functor, we want its right adjoint.

For an arbitrary morphism  $g : S \rightarrow UH$  where  $S$  is a set and  $H$  a group, good candidates of the solution set are those subgroups generated by  $\text{im } g$ , note that the elements of  $\langle \text{im } g \rangle$  are all of the form  $g(s_1)^\alpha g(s_2)^\alpha \cdots g(s_n)^\alpha$  where  $\alpha = \pm 1$  and  $s_i$  are not necessarily different, i.e. every element of this generated subgroup is always a finite composition of elements in  $\text{im } g$ , so the cardinality of  $\langle \text{im } g \rangle$  is bounded by  $|S| + \aleph_0$ , for any  $g$ , for any  $H$ .

Further more, the number of group structures on  $|S| + \aleph_0$  is also bounded (by simple estimation). So, by the Axiom of Choice, we choose a group from each isomorphic class of those group structures and gather these representations up and obtain the solution set.

Finally, we get the free group functor.

## 07-14: Lefschetz principle and Ax-Grothendieck theorem

**Ax-Grothendieck theorem:** For a bunch of polynomials  $f_{i(t_1, \dots, t_n)} \in \mathbb{C}[t_1, \dots, t_n]$ , if they are all injective viewed as a function  $\mathbb{C}^n \rightarrow \mathbb{C}$ , then the composed polynomial function  $F(x) := (f_1(x), \dots, f_n(x)) : \mathbb{C}^n \rightarrow \mathbb{C}^n$  is automatically surjective (Note that when  $n = 1$  Ax-Grothendieck theorem is just equivalent to the algebraic closeness of  $\mathbb{C}$  and thus this theorem is a generalised version of algebraic closeness in some sense).

To prove it (from a model theory point of view), we need following theorems, for  $p$  prime or zero:

**$\mathbf{ACF}_p$  is complete:** Thus any algebraic closed field with same characteristic is elementary equivalent. (For proof see notes on 07-15)

**Lefschetz principle:** For  $\mathbf{ACF}_p$  the theory of algebraic closed field with characteristic  $p$  and a  $\mathcal{L}_{\text{ring}}$ -sentence  $\varphi$ , the following are equivalent:

1. For almost all primes  $p$ ,  $\mathbf{ACF}_p \models \varphi$ ;
2. For infinite many primes  $p$ ,  $\mathbf{ACF}_p \models \varphi$ ;
3.  $\mathbf{ACF}_0 \models \varphi$ ;
4.  $\mathbb{C} \models \varphi$ ;

*proof.*

- $1 \Rightarrow 2$ : Obvious;
- $2 \Rightarrow 3$ : Note that  $\mathbf{ACF}_0 := \mathbf{ACF} \cup \{(\forall x, px \neq 0) : p \text{ prime}\}$ , and every finite subtheory of  $\mathbf{ACF}_0$  is satisfiable (the characteristic of a field is the *smallest* number  $p$  such that  $\forall x, px = 0$ ) by the models of  $\mathbf{ACF}_p$  for some big enough prime  $p$ ;
- $3 \Rightarrow 1$ : Now we play a trick: proof by contrapositive. So we are now trying to prove  $(\neg(1) \text{ implies } \neg(3))$ , by definition  $\neg(1)$  means “For infinite many primes  $p$ ,  $\mathbf{ACF}_p \models \neg\varphi$ ”, which implies  $\mathbf{ACF}_0 \models \neg\varphi$  by  $(2 \Rightarrow 3)$ ;
- $3 \Leftrightarrow 4$ :
  - $3 \Rightarrow 4$ : By definition;
  - $4 \Rightarrow 3$ : Since  $\mathbf{ACF}_0$  is complete.

The main idea of proving Ax theorem by Lefschetz property is that the theorem itself is just a  $\mathcal{L}_{\text{ring}}$ -sentence  $\varphi$ , so to prove  $\mathbb{C} \models \varphi$ , by Lefschetz principle it suffices to prove  $\mathbf{ACF}_p \models \varphi$  for infinite many primes  $p$ , further, by the completeness of  $\mathbf{ACF}_p$  it is equivalent to prove  $\overline{\mathbb{F}}_p = \bigcup_n \mathbb{F}_{p^n} \models \varphi$  for infinite many primes  $p$ .

And when restricted to a finite field, injective always implies surjective, so  $F$  is surjective on all  $\mathbb{F}_{p^n}$  since it is global injective, and thus surjective on  $\overline{\mathbb{F}}_p$ . The sentence  $\varphi$  is actually true for all primes  $p$  and by Lefschetz principle we are done.

*Thought.* Lefschetz principle is definitely useful: We can investigate “algebraic property” of any algebraic closed field by investigate  $\mathbb{C}$ , which can be studied by analytic methods.

## 07-15: $\mathbf{ACF}_p$ is complete

To prove it we need a lemma: Any extension of an *algebraic closed* field is actually an elementary extension of the base field (This is not trivial since there may be non-algebraic extensions, of course for algebraic extensions they actually must be isomorphic so everything is fine). All following numberings of theorems and corollaries are from 李文威《代数学方法卷一》.

*proof of lemma.* By assumption we have an extension  $E \hookrightarrow F$  where  $E$  is algebraic closed, which implies  $F$  is also algebraic closed due to the property of algebraic closed fields.

To produce something elementary equivalent to an given object, the immediately idea is Lowenheim-Skolem theorem: choose a large enough cardinal  $\kappa$  and we obtain two fields  $E'$  and  $F'$  with both cardinal  $\kappa$  and elementary equivalent to  $E$  and  $F$ , respectively. So for any  $\mathcal{L}_{\text{ring}} \cup E$ -sentence  $\varphi$ , we have  $E \equiv_E E'$ , and since  $F \equiv_F F'$  and  $F$  is an extension of  $E$  we have also  $F \equiv_E F'$ .

The last part of this proof is, as you have guessed, to show that  $E' \equiv_E F'$ , but thanks to algebraists, there are several theorems in field theory ensure that these two fields are actually  $E$ -isomorphic! Details: By (推论 8.8.7) we only need to show that transcendence degrees of these two extensions are equal  $\text{trdeg}_E E' = \text{trdeg}_E F'$ , let us denote the transcendence basis of  $E'$  and  $F'$  over the base field  $E$  as  $T_1$  and  $T_2$  respectively. By (命题 8.1.13) we have  $|E(T_1)| = |E'| = \kappa$  and  $|E(T_2)| = |F'| = \kappa$ . So  $|T_1| = |T_2| = \kappa$ , that is the transcendence degrees are equal. So we are done.

Of course the  $E$ -isomorphism between  $E'$  and  $F'$  preserves truth of  $\mathcal{L}_{\text{ring}} \cup E$ -sentences, so  $E' \equiv_E F'$ , since the elementary equivalent is a equivalence relation, finally  $E \equiv_E F$ .

Note that for any two fields  $X \models \mathbf{ACF}_p$  and  $Y \models \mathbf{ACF}_p$ , we can consider them as extensions of  $\overline{\mathbb{F}}_p$  which is algebraic closed, so by the lemma  $X$  and  $Y$  are all elementary equivalent to  $\overline{\mathbb{F}}_p$ , thus they are elementary equivalent.

Every two models of  $\mathbf{ACF}_p$  are elementary equivalent, this implies  $\mathbf{ACF}_p$  itself is indeed complete.

*Remark.* There is another “more model-theoretic” proof based on Vaught’s test, which claim that if a theory has only infinite models and is  $\kappa$ -categorical for an infinite cardinal  $\kappa$ , then it is complete. (Indeed  $\mathbf{ACF}_p$  is  $\kappa$ -categorical for any uncountable  $\kappa$ ). This method do not need the cute lemma in our proof.

## 07-30: $\mathbf{Grp}$ is cocomplete

That’s another application of the famous Adjoint Functor Theorem.

It is well known that for any small category  $J$  and  $X$ , the colimit functor  $\text{colim}_J : [J, X] \rightarrow X$  is the **left adjoint** of the constant functor  $\Delta : X \rightarrow [J, X]$ , and thus we are only need to apply the Adjoint Functor Theorem to  $\Delta : \mathbf{Grp} \rightarrow [J, \mathbf{Grp}]$ .

- Show that the domain of  $\Delta$  is **complete**: This is an elementary construction.

- Show that there exists a solution class: For  $X : J \rightarrow \mathbf{Grp}$ , define  $\lambda := |\coprod_{j \in J} X_j|$ , obviously there are only “a few” groups whose size is smaller than  $\lambda$  and all those groups form a **set**  $\{G_k\}$ , of course module isomorphism.
- Now we claim that  $\{G_k\}$  is a solution class: Indeed, for any other morphism  $\varphi \in (X \downarrow \Delta)$ , i.e. any natural transformation  $\varphi : X \rightarrow \Delta_H$  where  $H$  is a group, the size of the subgroup generated by  $\bigcup \varphi_j(X_j)$  is smaller than  $\lambda$  and thus this subgroup is isomorphic to  $G_k$  for some  $k$ , and thus we obtain a bunch of inclusions  $X_j \hookrightarrow G_k$ , and since  $\varphi$  is a natural transformation these inclusions form a natural transformation  $X \Rightarrow \Delta_{G_k}$ . Since the group  $H$  is arbitrary, we are done.

By the Adjoint Functor Theorem,  $\Delta$  has a left adjoint, which is definitely isomorphic to the colimit functor based on  $J$ .
